

## Topic 4 Classifying Elements

### Element Symbols

History of Chemical Symbols - [http://www.vanderkrogt.net/elements/chemical\\_symbols.html](http://www.vanderkrogt.net/elements/chemical_symbols.html)

New elements continue to be discovered. Finding a pattern in an unknown helps scientists to organize ideas and information. It also helps scientists to interpret what the information means and explain these ideas, based on what they have learned.

Early chemists used **symbols** of the sun and the planets to identify the elements known to them. This later was a problem, when more elements were discovered, because they ran out of planets.

Metal	gold	silver	iron	mercury	tin	copper	lead
Symbol							
Celestial Body	Sun	Moon	Mars	Mercury	Jupiter	Venus	Saturn

**John Dalton** developed a new set of symbols in the early 1800's to improve communication between chemists.

Symbol						
Element	hydrogen	oxygen	carbon	gold	silver	mercury

#### *Dalton's 1808AD symbols and formulae.*

 Hydrogen	 Soda	 Ammonia
 Nitrogen	 Pot Ash	 Olefiant
 Carbon	 Oxygen	 Carbonic Oxide
 Sulphur	 Copper	 Carbonic Acid
 Phosphorus	 Lead	 Sulphuric Acid
 Alumina	 Water

**Berzelius** later revised **Dalton's** symbols by replacing them with **letters**, instead of pictures. He represented the elements by their first letter (capitalized) or their first two letters (first one capitalized and the second letter lower case).

Elements were listed in order of their atomic mass. **Atomic mass** is the mass of one atom of an element. It is represented in **atomic mass units (amu)**.

John Newland's "**law of octaves**" identified the pattern in which the properties of the elements seemed to repeat at regular intervals, similar to the octave scale in music.

Demitri Mendeleev later revised the pattern in 1869, when he organized the elements into the first periodic table.

### Different Kinds of Elements

One way of classifying elements is to sort them into categories, based on their distinct properties. Long before anyone knew any detail about the atoms or any of the periodic properties the elements were divided into two broad categories → metals and non-metals.

Distinct properties of *metals* were malleability and ductility, shiny luster and were solid at room temperature (except mercury).

*Non-metals*: some were gases, solids or liquids; solid non-metals are brittle; they are flexible, dull and non-conductors of electricity or heat. In-between elements were called '*metalloids*', having properties of both metals and non-metals.

- Transition Metals** - The 38 elements in groups 3 to 12 are called transition metals. The only elements in this group known to produce a magnetic field are iron, cobalt and nickel.
- Other Metals** - There are 7 elements considered "other metals" in groups 13 to 15. All these elements are solid with a high density. Examples are tin, aluminum and lead.
- Metalloids** - These elements have both metal and non-metal properties. Some of them are semi-conductors, which means, they can carry an electrical charge under special conditions. Metalloids are great for computers and calculators.
- Non-Metals** - These fall into groups 14 to 16 in the periodic table. They can't conduct heat or electricity very well and are brittle. They also can't be made into wire or sheets. At room temperature, non-metals turn into gasses and solids.
- Rare Earth Elements** - There are 30 rare earth elements. Many of them are synthetic or man-made. They're found in group three of the periodic table and the sixth and seventh groups.

### Chemical Families

Chemical family is a term used to describe a group of related elements that have similar properties.

- Alkali Metals** - These are group 1 in the periodic table. They don't occur freely in nature and are softer than most metals. Like all metals, they are great heat conductors and can even explode if exposed to water – they are **very reactive** and need special storage. They easily give off an unpaired electron by forming a compound.
- Alkaline Earth Metals** - These are group 2 in the periodic table. Because they're extremely **reactive**, they aren't found freely in nature. An example of an alkaline earth metal is radium.
- Noble Gases** - The 6 noble gases are in group 18. All of them have the maximum number of electrons possible in their outer shell which makes them **stable**. Examples of noble gases are helium, neon and krypton.
- Halogens** - All 5 halogens are non-metallic elements. Compounds that contain halogen are called '**salts**'. At room temperature, they are in three states of matter: solid, liquid and gas.
